

GENERAL DESCRIPTION

The 83058I is a low skew, 8:1, Single-ended Multiplexer and a member of the family of High Performance Clock Solutions from IDT. The 83058I has eight selectable single-ended clock inputs and one single-ended clock output. The output has a V_{DDO} pin which may be set at 3.3V, 2.5V, or 1.8V, making the device ideal for use in voltage translation applications. An output enable pin places the output in a high impedance state which may be useful for testing or debug purposes. The device operates up to 250MHz and is packaged in a 16 TSSOP package.

FEATURES

- 8:1 single-ended multiplexer
- Q nominal output impedance: 7Ω ($V_{DDO} = 3.3V$)
- Maximum output frequency: 250MHz
- Propagation delay: 3ns (maximum), $V_{DD} = V_{DDO} = 3.3V$
- Input skew: 225ps (maximum), $V_{DD} = V_{DDO} = 3.3V$
- Part-to-part skew: 475ps (maximum), $V_{DD} = V_{DDO} = 3.3V$
- Additive phase jitter, RMS: 0.19ps (typical), 3.3V/3.3V
- Operating supply modes:
 V_{DD}/V_{DDO}
 3.3V/3.3V
 3.3V/2.5V
 3.3V/1.8V
 2.5V/2.5V
 2.5V/1.8V
- -40°C to 85°C ambient operating temperature
- Available in lead-free (RoHS 6) package

ADDITIVE PHASE JITTER

The spectral purity in a band at a specific offset from the fundamental compared to the power of the fundamental is called the **dBc Phase Noise**. This value is normally expressed using a Phase noise plot and is most often the specified plot in many applications. Phase noise is defined as the ratio of the noise power present in a 1Hz band at a specified offset from the fundamental frequency to the power value of the fundamental. This ratio is expressed in decibels

(dBm) or a ratio of the power in the 1Hz band to the power in the fundamental. When the required offset is specified, the phase noise is called a **dBc** value, which simply means dBm at a specified offset from the fundamental. By investigating jitter in the frequency domain, we get a better understanding of its effects on the desired application over the entire time record of the signal. It is mathematically possible to calculate an expected bit error rate given a phase noise plot.

As with most timing specifications, phase noise measurements has issues relating to the limitations of the equipment. Often the noise floor of the equipment is higher than the noise floor of the device.

This is illustrated above. The device meets the noise floor of what is shown, but can actually be lower. The phase noise is dependent on the input source and measurement equipment.

RECOMMENDATIONS FOR UNUSED INPUT PINS

INPUTS:

CLK INPUTS

For applications not requiring the use of a clock input, it can be left floating. Though not required, but for additional protection, a 1k Ω resistor can be tied from the CLK input to ground.

LVC MOS CONTROL PINS

All control pins have internal pull-ups or pull-downs; additional resistance is not required but can be added for additional protection. A 1k Ω resistor can be used.
